# Today's Lecture

- Generalized linear models (GLMs)
- Logistic regression

[Note: more on logistic regression can be found in the OpenIntro textbook, Chapter 8. These slides are based, in part, on the slides from OpenIntro.]

# Regression so far ...

At this point we have covered:

- Simple linear regression
  - Relationship between numerical response and a numerical or categorical predictor
- Multiple regression
  - Relationship between numerical response and multiple numerical and/or categorical predictors
  - What to do when the relationships with the predictors are complex (nonlinear, skewed distribution, interactions, confounding, etc.)

What we haven't covered is what to do when the response is not continuous (i.e. categorical, count data, etc.)

# Example - Birdkeeping and Lung Cancer

A 1972 - 1981 health survey in The Hague, Netherlands, discovered an association between keeping pet birds and increased risk of lung cancer. To investigate birdkeeping as a risk factor, researchers conducted a case-control study of patients in 1985 at four hospitals in The Hague (population 450,000). They identified 49 cases of lung cancer among the patients who were registered with a general practice, who were age 65 or younger and who had resided in the city since 1965. They also selected 98 controls from a population of residents having the same general age structure.

Ramsey, F.L. and Schafer, D.W. (2002). The Statistical Sleuth: A Course in Methods of Data Analysis (2nd ed)

# Example - Birdkeeping and Lung Cancer - Data

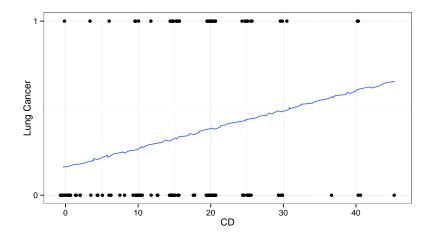

```
library(Sleuth3)
birds = case2002
head(birds)
```

##		LC	FM	SS	BK	$\mathbb{A}\mathbb{G}$	YR	CD
##	1	LungCancer	Male	Low	Bird	37	19	12
##	2	LungCancer	Male	Low	Bird	41	22	15
##	3	LungCancer	Male	High	NoBird	43	19	15
##	4	LungCancer	Male	Low	Bird	46	24	15
##	5	LungCancer	Male	Low	Bird	49	31	20
##	6	LungCancer	Male	High	NoBird	51	24	15

- LC Whether subject has lung cancer
- FM Sex of subject
- SS Socioeconomic status
- BK Indicator for birdkeeping
- AG Age of subject (years)
- YR Years of smoking prior to diagnosis or examination
- CD Average rate of smoking (cigarettes per day)

NoCancer is the reference response (0 or failure), LungCancer is the non-reference response (1 or success) - this matters for interpretation.

# Lung cancer as a function of cigarettes per day

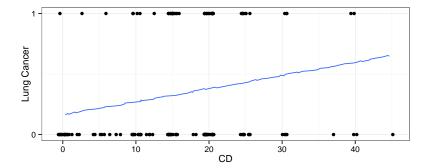

Generalized linear models

$$\mathbb{E}[Y|x] = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$$

Why not just use MLR when outcomes not continuous?

• Linearity assumption may be more unreasonable than usual.

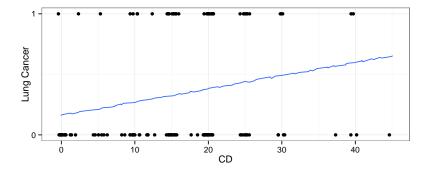

Generalized linear models

$$\mathbb{E}[Y|x] = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$$

Why not just use MLR when outcomes not continuous?

• Equal variance assumption often violated  $(Var[Y|x] = \sigma^2)$ .

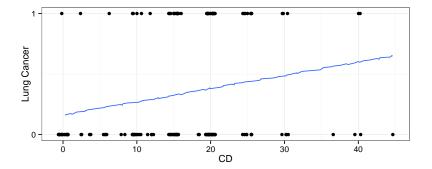

Generalized linear models

$$\mathbb{E}[Y|x] = \beta_0 + \beta_1 X_1 + \dots + \beta_p X_p$$

Why not just use MLR when outcomes not continuous?

• Assumption of normal errors explicitly violated.

# Generalized linear models: defined

All generalized linear models have the following three characteristics:

- 1. A probability distribution describing the outcome variable e.g.  $Y \sim \text{Bernoulli}(p) \longrightarrow \mathbb{E}[Y|p] = p$ .
- 2. A linear model

- 3. A link function that relates the linear model to the parameter of the outcome distribution
  - $g(\mathbb{E}[Y]) = g(p) = \eta$  or  $\mathbb{E}[Y] = p = g^{-1}(\eta)$

# Odds

Odds are another way of quantifying the probability of an event, commonly used in gambling (and logistic regression).

For some event E,

$$\mathsf{odds}(E) = rac{P(E)}{P(E^c)} = rac{P(E)}{1 - P(E)}$$

Similarly, if we are told the odds of E are x to y then

$$odds(E) = \frac{x}{y} = \frac{x/(x+y)}{y/(x+y)}$$

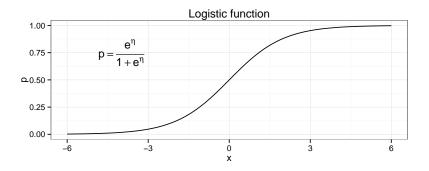

which implies

$$P(E) = x/(x+y), \quad P(E^{c}) = y/(x+y)$$

### Logistic regression has log(odds) as the link

A logistic regression model can be defined as follows:

$$Y_{i}|\mathbf{x}_{i} \sim \text{Bernoulli}(p_{i})$$
$$\mathbb{E}[Y_{i}|\mathbf{x}_{i}] = Pr(Y_{i} = 1|\mathbf{x}_{i}) = p_{i}$$
$$g(p_{i}) = logit(p_{i}) = \log \frac{p_{i}}{1 - p_{i}}$$
$$logit(\mathbb{E}[Y_{i}|\mathbf{x}_{i}]) = logit(p_{i}) = \eta = \beta_{0} + \beta_{1}X_{i1} + \dots + \beta_{p}X_{ip}$$

# Example - Birdkeeping and Lung Cancer - Model

 $logitPr(LC = 1 | \mathbf{x}) = \beta_0 + \beta_1 BK + \beta_2 FM + \beta_3 SS + \beta_4 AG + \beta_5 YR + \beta_6 CD$ 

# Example - Birdkeeping and Lung Cancer - Interpretation

#### summary(lm1)\$coef

##		Estimate	Std. Error	z value	Pr( z )
##	(Intercept)	-1.27064	1.82531	-0.6961	0.4863515
##	BKBird	1.36259	0.41128	3.3131	0.0009227
##	FMMale	-0.56127	0.53116	-1.0567	0.2906525
##	SSLow	-0.10545	0.46885	-0.2249	0.8220502
##	AG	-0.03976	0.03548	-1.1205	0.2625028
##	YR	0.07287	0.02649	2.7511	0.0059403
##	CD	0.02602	0.02552	1.0193	0.3080553

Keeping all other predictors constant then,

- The odds ratio of getting lung cancer for bird keepers vs non-bird keepers is exp(1.3626) = 3.91.
- The odds ratio of getting lung cancer for an additional year of smoking is exp(0.0729) = 1.08.

# What do the numbers not mean ...

The most common mistake made when interpreting logistic regression is to treat an odds ratio as a ratio of probabilities.

Bird keepers are *not* 4× more likely to develop lung cancer than non-bird keepers.

This is the difference between relative risk and an odds ratio.

$$RR = \frac{P(\text{disease}|\text{exposed})}{P(\text{disease}|\text{unexposed})}$$

 $OR = \frac{P(\text{disease}|\text{exposed})/[1 - P(\text{disease}|\text{exposed})]}{P(\text{disease}|\text{unexposed})/[1 - P(\text{disease}|\text{unexposed})]}$ 

## Important notes about GLMs

On logistic regression in particular...

- There are other link functions for binary data (e.g. probit, cloglog).
- Other, less parameteric methods may be appropriate here too

   e.g. CART, random forests, classification algorithms.

#### Beyond the scope of this course, but interesting topics...

- How are logistic models (and other GLMS) fitted?
- Can we perform the same kind of model diagnostics to determine whether a model provides a good fit to data?
- ROC curves and classification rules
