Focus on covariance

$$I = \begin{bmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & 1 \end{bmatrix}$$

- We've extensively used OLS for the model

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

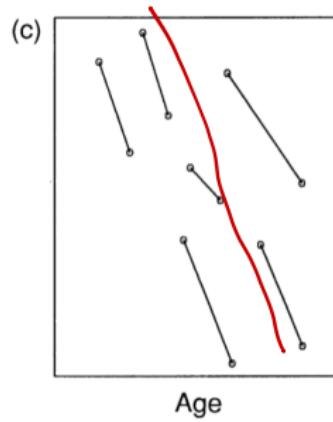

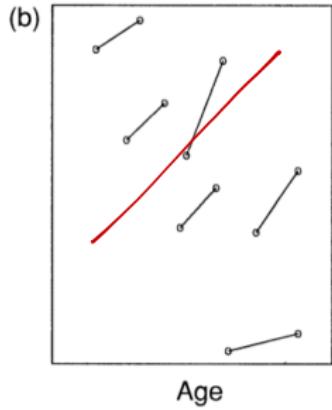

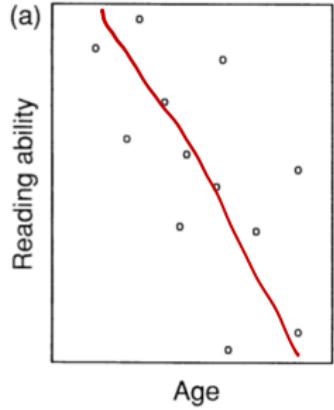

where $E(\boldsymbol{\epsilon}) = 0$ and $\text{Var}(\boldsymbol{\epsilon}) = \sigma^2 I$

- We are now more interested in the case of $\text{Var}(\boldsymbol{\epsilon}) = \sigma^2 V$
- ~~WLS and GLS were useful in this setting, but required a known V matrix~~

Longitudinal data

- Data is gathered at multiple time points for each study participant
- Repeated observations / responses
- Longitudinal data regularly violates the “independent errors” assumption of OLS
- LDA allows the examination of changes over time (aging effects) and adjustment for individual differences (subject effects)

Some hypothetical data

Notation

$$\vec{y} = \begin{bmatrix} y_{11} \\ y_{12} \\ \vdots \\ y_{1J_1} \\ y_{21} \\ \vdots \\ y_{2J_2} \end{bmatrix} \rightarrow \vec{y}_1 \quad \vec{y}_2$$

- We observe data y_{ij}, x_{ij} for subjects $i = 1, \dots, I$ at visits $j = 1, \dots, J_i$ \Rightarrow unbalanced design $\text{if } J_i = J \Rightarrow$ balanced design
- Vectors \mathbf{y}_i and matrices \mathbf{X}_i are subject-specific outcomes and design matrices
- Total number of visits is $n = \sum_{i=1}^I J_i$
- For subjects i , let

$$\mathbf{y}_i = \mathbf{X}_i \boldsymbol{\beta} + \boldsymbol{\epsilon}_i$$

where $\text{Var}(\boldsymbol{\epsilon}_i) = \sigma^2 V_i$ ~~$\not\subset \mathbb{L}^2$~~

Notation

- Overall, we pose the model

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\text{Var}(\boldsymbol{\epsilon}) = \sigma^2 V$ and

$$V = \begin{bmatrix} & & & & \\ & V_1 & 0 & \dots & 0 \\ & 0 & V_2 & \dots & 0 \\ \vdots & \vdots & \ddots & & \\ 0 & 0 & & V_I & \end{bmatrix}$$

block diagonal

The diagram shows a large square matrix divided into four quadrants by red lines. The top-left quadrant contains a smaller square matrix labeled 'A'. The other three quadrants are empty, representing zero matrices.

Covariates

The covariates $\mathbf{x}_i = x_{ij1} \dots x_{ijp}$ can be

- Fixed at the subject level – for instance, sex, race, fixed treatment effects
- Time varying – age, BMI, smoking status, treatment in a cross-over design

Motivation

Why bother with LDA?

- Correct inference
- More efficient estimation of shared effects
- Estimation of subject-level effects / correlation
- The ability to “borrow strength” – use both subject- and population-level information
- Repeated measures is a very common feature of real data!

Example dataset

An example dataset comes from the Multicenter AIDS Cohort Study (CD4.txt).

- 366 HIV+ individuals
- Observation of CD4 cell count (a measure of disease progression)
- Between 1 and 11 observations per subject (1888 total observations)

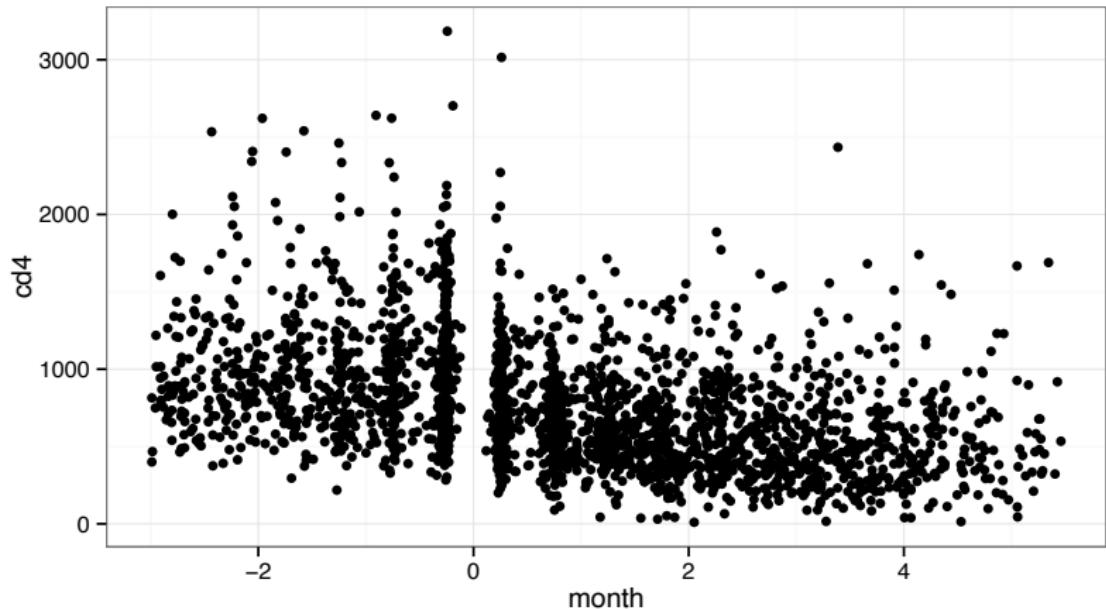

CD4 dataset

```
data <- read.table("CD4.txt", header = TRUE)  
head(data, 15)
```

##	month	cd4	age	packs	drug	part	ceased	ID
## 1	-0.7420	548	6.57	0	0	5	8	10002

## 15	1.4127	704	2.64	0	1	5	21	10029

CD4 dataset

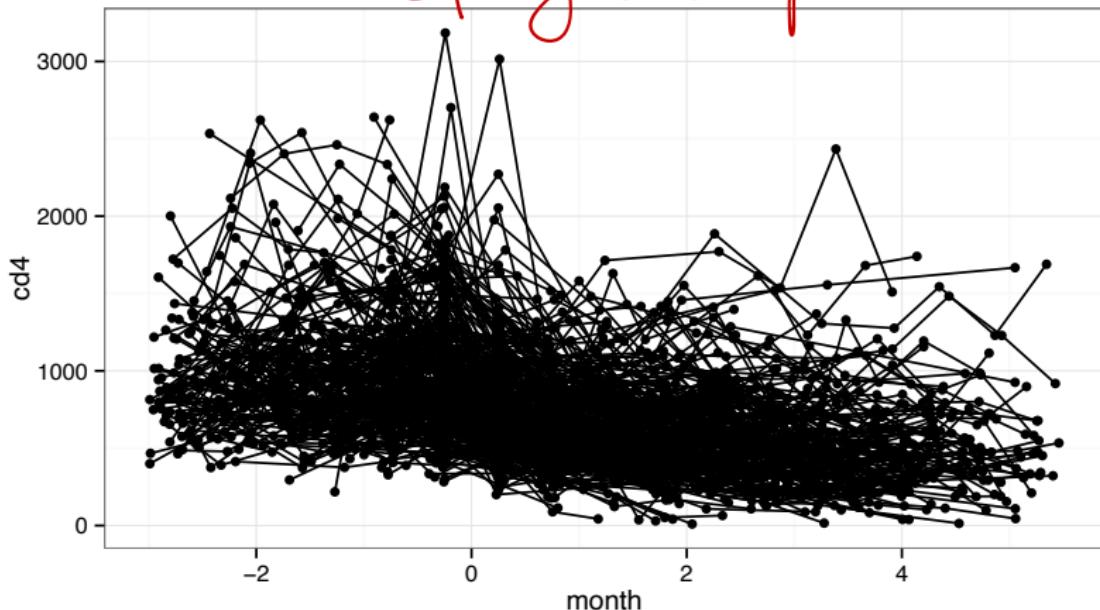

```
qplot(month, cd4, data=data)
```

CD4 dataset

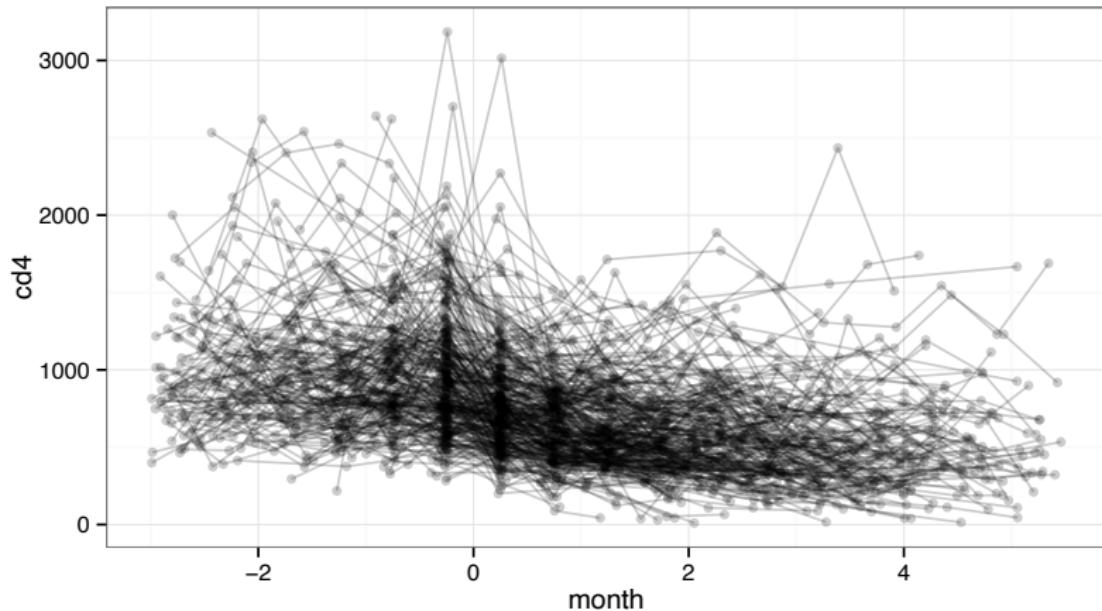

```
qplot(month, cd4, data=data, geom=c("point", "line"),  
      group=ID)
```

spaghetti plot

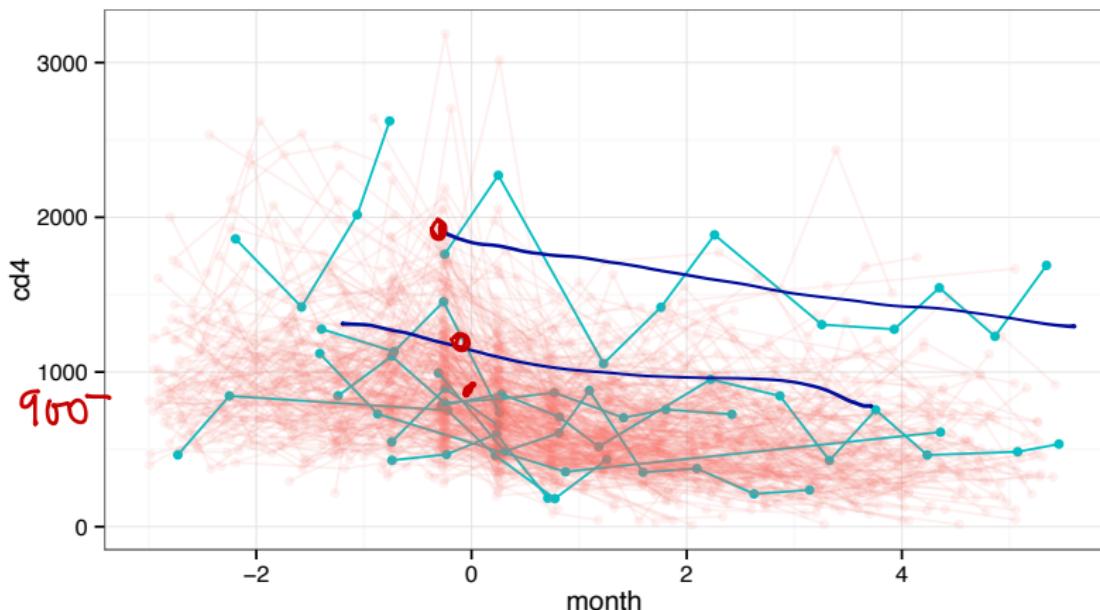

CD4 dataset

```
qplot(month, cd4, data=data, geom=c("point", "line"),  
      group=ID, alpha=I(.2))
```

CD4 dataset

```
IDS <- unique(data$ID)
data$highlight <- as.factor(data$ID %in% IDS[1:10])
qplot(month, cd4, data=data, geom=c("point", "line"),
      group=ID, color=highlight, alpha=highlight) +
  theme(legend.position="none")
```

Visualizing covariances

Suppose the data consists of three subjects with four data points each.

- In the model

$$\mathbf{y}_i = \mathbf{X}_i\beta + \epsilon_i$$

where $\text{Var}(\epsilon_i) = \sigma^2 V_i$, what are some forms for V_i ?

unstructured

$$\begin{bmatrix} 1 & 2 \\ 1 & \rho_1 & \rho_2 & \rho_3 \\ 1 & \rho_4 & \rho_5 & \rho_6 \\ 1 & & & 1 \end{bmatrix}$$

uniform/exchangeable

$$\begin{bmatrix} 1 & \rho & \rho & \rho \\ \rho & 1 & \rho & \rho \\ \rho & \rho & 1 & \rho \\ \rho & \rho & \rho & 1 \end{bmatrix}$$

Auto-regressive

$$\begin{bmatrix} 1 & \rho^1 & \rho^2 & \rho^3 \\ & 1 & \rho^1 & \rho^2 \\ & & 1 & \rho^1 \\ & & & 1 \end{bmatrix}$$

$A - R$

Approaches to LDA

We'll consider two main approaches to LDA

- **Marginal models**, which focus on estimating the main effects and variance matrices but don't introduce subject effects
 - "Simplest" LDA model, just like cross-sectional data
 - Requires new methods, like GEE, to control for variance structure
 - Arguably easier incorporation of different variance structures
- **Random effects models**, which introduce random subject effects (i.e. effects coming from a distribution, rather than from a "true" parametric model)
 - "Intuitive" model descriptions
 - Explicit estimation of variance components
 - Caveat: can change parameter interpretations

First problem: exchangeable correlation

Start with the model where

$$V_i = \begin{bmatrix} 1 & \rho & \dots & \rho \\ \rho & 1 & \dots & \rho \\ \vdots & \vdots & \ddots & \\ \rho & \rho & & 1 \end{bmatrix}$$

This implies

- $\text{var}(y_{ij}) = \sigma^2$
- $\text{cov}(y_{ij}, y_{ij'}) = \sigma^2 \rho$ ↪²
- $\text{cor}(y_{ij}, y_{ij'}) = \rho$

Marginal model

The marginal model is

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where

- $\text{Var}(\boldsymbol{\epsilon}) = \sigma^2 V, \neq \sigma^2 I \quad (\text{OLS})$

-

$$V_i = \begin{bmatrix} 1 & \rho & \dots & \rho \\ \rho & 1 & \dots & \rho \\ \vdots & \vdots & \ddots & \\ \rho & \rho & & 1 \end{bmatrix}$$

Tricky part is estimating the variance of the parameter estimates
for this new model.

SEs

Fitting a marginal model using GEE

Generalized Estimating Equations provide a semi-parametric method for fitting a marginal model that takes into account the correlation between observations.

$$\mathbb{E}[CD4_{ij} | month] = \beta_0 + \beta_1 \cdot month$$

With GEE, assume V_i is exchangeable.

```
require(gee)
linmod <- lm(cd4~month, data=data)
geemod <- gee(cd4~month, data=data, id=ID,
               corstr="exchangeable")
```

Fitting a marginal model using GEE

$$\mathbb{E}[CD4_{ij} | month] = \beta_0 + \beta_1 \cdot month$$

With GEE, assume V_i is exchangeable.

```
summary(linmod)$coef
```

	Estimate	Std. Error	t value	Pr(> t)
## (Intercept)	838.82	8.136	103.11	0.000e+00
## month	-88.95	3.964	-22.44	2.628e-101

```
summary(geemod)$coef
```

	Estimate	Naive S.E.	Naive z	Robust S.E.	Robust z
## (Intercept)	836.93	14.794	56.57	15.261	54.84
## month	-99.73	3.429	-29.08	5.056	-19.73

Random effects model

A random intercept model with one covariate is given by

$$y_{ij} = \underbrace{\beta_0}_{\text{---}} + \underbrace{b_i}_{\text{---}} + \underbrace{\beta_1 x_{ij}}_{\text{---}} + \underbrace{\epsilon_{ij}}_{\text{---}}$$

↑
random intercept +

where

- $b_i \sim N[0, \tau^2]$
- $\epsilon_{ij} \sim N[0, \nu^2]$

For exchangeable correlation and continuous outcomes, the random intercept model is equivalent to the marginal model.

Under this model

- $\text{var}(y_{ij}) =$
- $\text{cov}(y_{ij}, y_{ij'}) =$
- $\text{cor}(y_{ij}, y_{ij'}) = \rho =$

Fitting a random effects model

```
require(lme4)
memod <- lmer(cd4 ~ (1 | ID) + month, data = data)
summary(memod)$coef
```

random intercept

	Estimate	Std. Error	t value
## (Intercept)	836.96	14.652	57.12
## month	-99.66	3.448	-28.90

```
summary(geemod)$coef
```

	Estimate	Naive S.E.	Naive z	Robust S.E.	Robust z
## (Intercept)	836.93	14.794	56.57	15.261	54.84
## month	-99.73	3.429	-29.08	5.056	-19.73

Conclusion

Today we have..

- introduced longitudinal data analysis.
- defined and fitted Marginal and Random Effects models.
